Chief, Reports Division, ORR
THRU: Chief, Materials Division, ORR
Chief, Food and Agriculture Branch, D/H, ORR

IP-21.9.3, Extent and Effects of 1952 Crop Failures in Eastern Europe

- 1. This Branch is an attempt to fulfill OCI requirements on the above subject, has made an effort to skim the surface of the incomplete M/AC project 21.9.1. The attached rough draft deals primarily with generalities of the Eastern European food situation as an aggregate--no attempt has been made to analyze the specifics.
- 2. M/AG's 21.9.1 project will give much fuller treatment to the entire food supply situation in each individual Satellite. It is suggested that OCI be sent an advance copy of 21.9.1 when it leaves M/AG at the end of the second quarter. Also, commodity studies forthcoming this quarter will give a more detailed analysis of individual commodities—their production and utilization.
- 3. In reference to OCI's memorandum of 16 January 1953, their request has been answered with exception of 4b. M/AU does not have complete 1953 trade agreements for the Eastern European Satellites. Satellite trade agreements with Russia and China merely mention commodities and not actual quantities. A study of the EE/USSR agricultural commodity trade is continuing in M/AU.
- 4. The Food and Agriculture Branch will be available to offer any assistance to CCI that may be desired on agricultural problems within the Soviet Bloc. It is hoped that the pressure of work in the future will permit a more expeditious handling of CCI requests.

EXTENT AND EFFECTS OF 1952 CROP FAILURES IN RASTERN EUROPE

I. 1952 Crop Production. **

Unfavorable weather conditions throughout the greater part of Eastern Europe during the 1951-52 growing season significantly reduced the yields of corn, potatoes, vegetables, sugar beets, and, to a lesser extent, wheat and rye crops. A prolonged drought which occurred over most of the area during July and August substantially reduced yields of corn, potatoes, sugar beets, and late-planted vegetables. Previously, a drought in the autumn of 1951 had delayed sowing and germination of winter-sown grains (wheat and rye), and an unseasonable frost in mid-May 1952 damaged spring vegetables and retarded grains. Corn was actually killed by the frost in some areas and was replanted, provided seed was available. Sugar beet and, even more so, potato yields were further reduced, following the mid-summer drought when early freezing temperatures and snow caught these crops in the ground or in open storage in the area from Hungary morth to Poland.

In 1952, total grain production in Eastern Europe has been estimated at only 83 percent of 1951. In southeastern Europe, however, total grain production was much less than in the northern area (Poland, GR, and Czecheslovakia) because of the 40- to 50-percent reduction in the production of corn. Sugar, potatoes, and vegetable oil production for 1952 is estimated at 65 percent, 84 percent, and 75 percent of 1951, respectively. The only commodities showing an increase in production over 1951 are meat and animal fats. This is because of the excessive slaughtering of livestock, which is thought to have taken place in most of the Satellites as a result of the shortfall in the production of fodder and forage crops.

II. Food Supplies Available For Consumption.

In both the prewar and postwar periods, when drought has not occurred, the

Eastern European Satellites, with few exceptions, have produced enough food products
to be self-sufficient. During the postwar period, however, although production of
agricultural commodities is less than prewar and the populations are greater, the

Communist regimes have attempted to export food commodities in order to finance
their grandices industrialization progress. This has had the affect of reducing
both the total per capita caloric intake and the quality of the diet, which was
below Western standards in the prewar period.

^{*} Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania. ** See Table 1, p.6, below, for production of selected commodities by individual Eastern European Satellites.

Tables 3 through 10% show the total gress supply of food available for consumption purposes, which is the result obtained by deducting nonfood uses from the total supply. The remainder, or net supply, is, therefore, the base from which per capita availability can be ascertained. With the exception of meat, gross food availabilities for 1952-53 are less for all categories of food as compared with 1951-52, and even for meat they are less in comparison with prewar. The increased availability of meat in 1952-53 is a direct result of excessive slaughtering. The possibility, however, does exist that the Satellites may export and/or stockpile additional quantities of meat with a resultant decrease in the amount available for human consumption.

III. Per Capits Food Availability.

With few country exceptions (see Tables 3 through 10), per capita availability of foods considered shows a decline in 1951-52 and 1952-53 from prewar, with the exception of grains and potatoes. As a means of attempting to compare total food intake, calories have been used as a common unit of measurement. This only shows total calories and not the ratio of food composing the diet. Cenerally speaking (see Tables 3 through 10), the postwar per capita consumption of meat, animal fats, vegetable oils, and milk (not shown) have decreased as compared with prewar, while the per capita consumption of grain and, in some countries, potatoes have increased. As a result the diet is now made up of a higher percentage of starchy foods instead of high energy producing foods which are more desirable for industrial workers.

The 1952-53 food situation is one of the worst that the Communist regimes have had to face since the immediate postwar years. Over-all per capita consumption, as seem in Table 2,000 indicates decreased in the 1952-53 calcric intake as compared with 1951-52 from it percent in Poland to 24 percent in Rumania.0000 It is dangerous to take these statistics at face value; they only show average per capita availabilities with no indication of breakdown between self suppliers and non-self suppliers. Also, with specific reference to Hungary, the assumption was made that exports of bread grains would be curtailed and placed into consumption channels to alleviate partially the deficit supply of other commodities. Therefore, the total average calcric picture shows only a slight drop. The composition of the diet, however, has changed. The major grain shortage in Hungary is in feed grains, a shortage which will adversely affect livestock numbers.

^{*} Pp. 8-15, below.

we P. 7, below.

The percentage decrease would actually be greater if vegetables, eggs, cheese, and pulses had been considered. They normally amount to 10 percent of the caloric intake, but in 1952-53 they would be significantly less.

Approved For Release 2002/62/41 - CIA-RDP79T01049A000800060001-6

Food shortages will show among the industrial workers first.* Despite elaborate procurement and marketing systems set up by the Communist regimes to supply the industrial workers, they have not been able to obtain the desired quantities of food from the peasants even during years of more normal production, such as 1951-52. This has caused shortages of commodities such as meat, fats, and vegetable oils among the working classes. In addition, the governments dependent upon agricultural exports to finance their industrialization programs have exported food commodities at the expense of the workers, who have had to make the sacrifice.

The land reform in Eastern Europe broke up the large estates, which were the major source of surplus agricultural commodities for the cities and not the small land-owners upon when they are now dependent. Collectives and State farms are supposed to take up the slack, but, as of 1953, they are not in a position to supply the greater percentage of the urban requirements.

IV. Probable Effects of the 1952 Shortfall in Agricultural Production.

A. Foreign Trade.

Southeast Europe has depended upon the export of grain, meat, cileseds, tobacco, and other agricultural commodities to finance their industrialization programs as called for in the various country plans. The lack of these commodities in sufficient quantities will seriously hinder their industrialization program. Hungary has admitted that, as a result of the drought, she has been forced to reduce the 1953 industrial goals. Should forced exports take place, then the populations will suffer accordingly.

In the northern area of the Eastern Europe, Poland normally exports or has available 400 thousand to 500 thousand tons of grain, 300 thousand tons of sugar, and 30 thousand to 50 thousand tons of meat, while in 1952-53 there will only be an estimated 180 thousand tons of grain available and 180 thousand tons of sugar. East Germany and Czechoslovakia are the least dependent upon agricultural commodities to supply their foreign exchange; however, sugar is normally exported in sizable quantities (300 thousand to 400 thousand tons). The 1952-53 export availability has decreased to where there are probably only 180 thousand tons of sugar available from each country.

B. Industrial Production.

The low per capita caloric intake during 1952-53 may seriously affect the labor productivity. The high cost of food and the unavailability of high energy

^{*} Peasants living in the normally deficit areas of the Satellites will probably be on a near starvation diet level (particularly in Albania, Hungary, and Rumania), since it is unlikely that the governments will have sufficient supplies to supply these areas as well as industrial centers which receive top priority.

Approved For Release 2002/92/11 E RDP79T01049A000800060001-6

foods will increase the discentant of the workers. Production plans have not been fulfilled in the past, and this will continue as norms are increased and as the workers dist detoriorates. The discontent in Poland and Czechoslovakia has resulted in minor strikes, and in other Satellites much grumbling occurs among the working Improving the diet of the industrial worker will be one of the major problems facing the Satellite governments during the next few years. No relief appears to be in sight.

C. Stockpiling Program.

Although little is known about agricultural commodity stockpiling programs in Eastern Europe, it is known that East Gorzany presently has one in operation, and it is suspected that several other Satellites also have a ferm of stockpiling program. The drought will or should affect the quantities of food that will be available for stockpiling purposes in 1953. It is probable that sees of the countries may be forced to draw upon some of their stocks for the 1952-53 consumption year and temperarily discentinue the stockpiling program. It has been reported, however, that grains, meat, and sugar will again be stockpiled this year in East Germany, and sugar in Czechoslovakia.

D. Collectivization.

It is believed that the drought has had only a temporary affect of slowing down the drive to socialize new farms to one of consolidating previous gains, with the exception of Poland and East Germany. The drive to collectivize will be as much alive in the next few months as ever, but the intensification of the rate of collectivization may be semewhat less than in 1952 for Hungary and Czechoslovakia. The ability of the Satellites to mechanize will be a significant economic factor in determing future rates of collectivization. The drought has had the effect of raducing the ability of the government to finance imports and to manufacture of tractors and complementary equipment.

V. Food Export Potential of the USSR and China for 1952-53.

In 1952 the USSR and China both had normal or slightly above normal crop production for major food commodities. As shown in Table 11,24 the Soviet production of all crops in 1952 was larger than in 1951 and for some commodities approached prewar levels. China's production (see Table 12" "") of grains and potatoes was larger than in 1951, and potato production was larger than in prewar. There are

Strategic or military reserves.

we P. 16, below.

Approved For Release 2002/02/14 - CTA R P79T01049A000800060001-6

no statistics available on the exact amount of food that might possibly be made available for export to Eastern Europe from China. It is believed, however, that edible vegetable cileseds and some grain could be exported to Eastern Europe, provided that the USSR does not demand them.

According to Table 11,* the USSR would have sufficient quantities of grain and possibly of meat to relieve the food situation and livestock feed shortage im Eastern European countries. There has been, however, no reliable information indicating that the USSR has any intention of shipping over and above the normal amounts of grain and meat experted to Eastern European countries. The probability the USSR will give grant-in-aid to Eastern European countries. The probability does exist that the USSR may loan grain or other feedstuff to some of the Satellites as she did to Bulgaria in 1949. This grain was to have been repaid from the following year's harvest. To date there has been no reliable information on this form of help from the USSR to its Satellites.

[#] P. 16, below.

^{**} Csechoslovakia and East Germany claim to have each received in 1951 approximately 800,000 metric tons of grain from the USSR.
